

**Theorem:** Prove that Post Correspondence Problem (PCP) is undecidable

### **Post Correspondence Problem**

This problem is introduced by Emil Leon Post in 1946 [1]. Problem asks to find a match from the given collection of two faced dominos where each face of dominos contains strings. A two faced domino will look like:  $\begin{bmatrix} a \\ ab \end{bmatrix}$

So the collection of two faced dominos can be represented in a set as:

$$\left\{ \begin{bmatrix} a \\ ab \end{bmatrix}, \begin{bmatrix} b \\ ca \end{bmatrix}, \begin{bmatrix} ca \\ a \end{bmatrix}, \begin{bmatrix} a \\ ab \end{bmatrix}, \begin{bmatrix} abc \\ c \end{bmatrix} \right\}$$

If we choose a list of dominos from the dominos (repetition is allowed while choosing) set in such a way that concatenated of strings in one face must be same as concatenated string of other face. This list is called match. This problem asks us to find a match from any given set of two faced dominos.

In the above collection of two faced dominos, there exists a match because the string “abcaaabc” can be obtained by concatenating strings of each face of the dominos separately.

### **Problem Definition**

An instance of this problem can be expressed in mathematically as:

Let D be the collection of n dominos.

$$D = \left\{ \begin{bmatrix} u_1 \\ v_1 \end{bmatrix}, \begin{bmatrix} u_2 \\ v_2 \end{bmatrix}, \begin{bmatrix} u_3 \\ v_3 \end{bmatrix}, \dots, \begin{bmatrix} u_n \\ v_n \end{bmatrix} \right\}$$

And there exists match sequence  $k_1, k_1, k_2, k_3 \dots k_l$  where

$u_1 u_2 u_3 \dots u_l = v_1 v_2 v_3 \dots v_l$  (Concatenation of strings of one face is u and other face v) problem is to find the existence of match in D. Let

PCP = { <D> | D is the instance of the Post Correspondence Problem with a match }

### **Proof:**

Consider a Turing machine M to simulate this PCP's input string w can be represented as <M, w>.

$$M = (Q, \Sigma, \Gamma, \delta, q_0, q_{\text{accept}}, q_{\text{reject}})$$

If there is a match in the input string  $w$ , then Turing machine  $M$  halts in an accepting state. This halting state of Turing machine is an acceptance problem  $A_{TM}$ . We know that the acceptance problem  $A_{TM}$  is undecidable from proof mentioned in Sipser's book [1]. Therefore PCP problem is also undecidable.

If a Turing Machine  $M$  accepts input  $w$ , then the computation history of  $M$  gives us the accepting configuration, from which we can determine the instance  $D$  of the PCP problem has a match. How can we construct the instance  $D$  so that there exists a match and Turing Machine  $M$  halts in accept state on input  $w$ ? By choosing the dominos in such a way a concatenation of strings of each faces are same at each step of the selection. We can force the simulation of  $M$  to accept the  $w$ .

To force the simulation of  $M$ , we make 2 modifications to Turing Machine  $M$  and a one change to our PCP problem.

1.  $M$  on input  $w$  can never attempt to move tape head beyond the left end of the input tape.
2. If input is empty string  $\epsilon$  we use  $\_$
3. PCP problem starts the match with first domino  $\begin{bmatrix} u_1 \\ v_1 \end{bmatrix}$  This is called Modified PCP problem  
 $MPCP = \{ \langle D \rangle \mid D \text{ is an instance of PCP starts with first domino} \}$

*Construction Steps:*

1. Put  $\begin{bmatrix} \# \\ \#q_0w_1w_2..wn\# \end{bmatrix}$  into  $D^1$  as the first domino, where is instance of  $D^1$  is MPCP. A partial match is obtained in first domino is  $\#$  at one face is same  $\#$  symbol in other face.
2. Transition functions for Turing Machine  $M$  can have moves Left L, Right R  
 For every  $x, y, z$  in  $\Gamma$  tape alphabets and  $q, r$  in  $Q$  where  $q$  is not equal to  $q_{reject}$ .  
 If  $\delta(q, x) = (r, y, R)$  put the domino  $\begin{bmatrix} qx \\ by \end{bmatrix}$  into  $D^1$  and  $\delta(q, x) = (r, y, L)$  put the domino  $\begin{bmatrix} zqx \\ rzy \end{bmatrix}$  into  $D^1$
3. For every tape alphabets  $x$  in  $\Gamma$  put  $\begin{bmatrix} x \\ x \end{bmatrix}$  into  $D^1$   
 To mark the separation of each configurations put  $\begin{bmatrix} \# \\ \# \end{bmatrix}$  and  $\begin{bmatrix} \# \\ \_ \end{bmatrix}$  into  $D^1$
4. To read input alphabets  $x$  in  $\Gamma$  even after Turing Machine is accepting state put  $\begin{bmatrix} xqa \\ qa \end{bmatrix}$  and  $\begin{bmatrix} qax \\ qa \end{bmatrix}$   
 and  $\begin{bmatrix} qa\# \\ \# \end{bmatrix}$  into  $D^1$

These steps concludes the construction of  $D^1$  Since this a instance of MPCP, we need to convert this to PCP. So to convert to  $D$ , we consider the below dominos and strings matchings.

*Converting MPCP To PCP*

Let  $u = u_1, u_2, \dots, u_n$  be any string of input length  $n$  and modify these strings as

$$\$u = *u_1*u_2*u_3* \dots *u_n$$

$$u\$ = u_1* u_2* u_3* \dots u_n*$$

$$\$u\$ = * u_1* u_2* u_3* \dots u_n*$$

Let  $D$  be the set of two faced Dominos

$$D = \left\{ \left[ \begin{array}{c} u_1 \\ v_1 \end{array} \right], \left[ \begin{array}{c} u_2 \\ v_2 \end{array} \right], \left[ \begin{array}{c} u_3 \\ v_3 \end{array} \right], \dots, \left[ \begin{array}{c} u_n \\ v_n \end{array} \right] \right\} \text{ and } \left\{ \left[ \begin{array}{c} \$u_1 \\ \$v_1\$ \end{array} \right], \left[ \begin{array}{c} \$u_2 \\ \$v_2\$ \end{array} \right], \dots, \left[ \begin{array}{c} * \\ \_ \end{array} \right] \right\}$$

From above dominos collection, we could see only domino has partial match starts with  $\left[ \begin{array}{c} \$u_1 \\ \$v_1\$ \end{array} \right]$  and to place marker the end of inputs  $\left[ \begin{array}{c} * \\ \_ \end{array} \right]$  There by we can avoid stating explicit requirement of domino should start with first domino.

If number of configurations of the Turing machine does not lie within the value of  $qng^n$  [Lemma specified in Sipser's Book], then Turing machine is looping state. It does not halt.
